

# Understanding the Downward Trend in Labor Income Shares

*Mai Dao, Mitali Das (team lead), Zsoka Koczan and Weicheng Lian,  
with contributions from Jihad Dagher and support from Ben Hilgenstock and Hao Jiang*

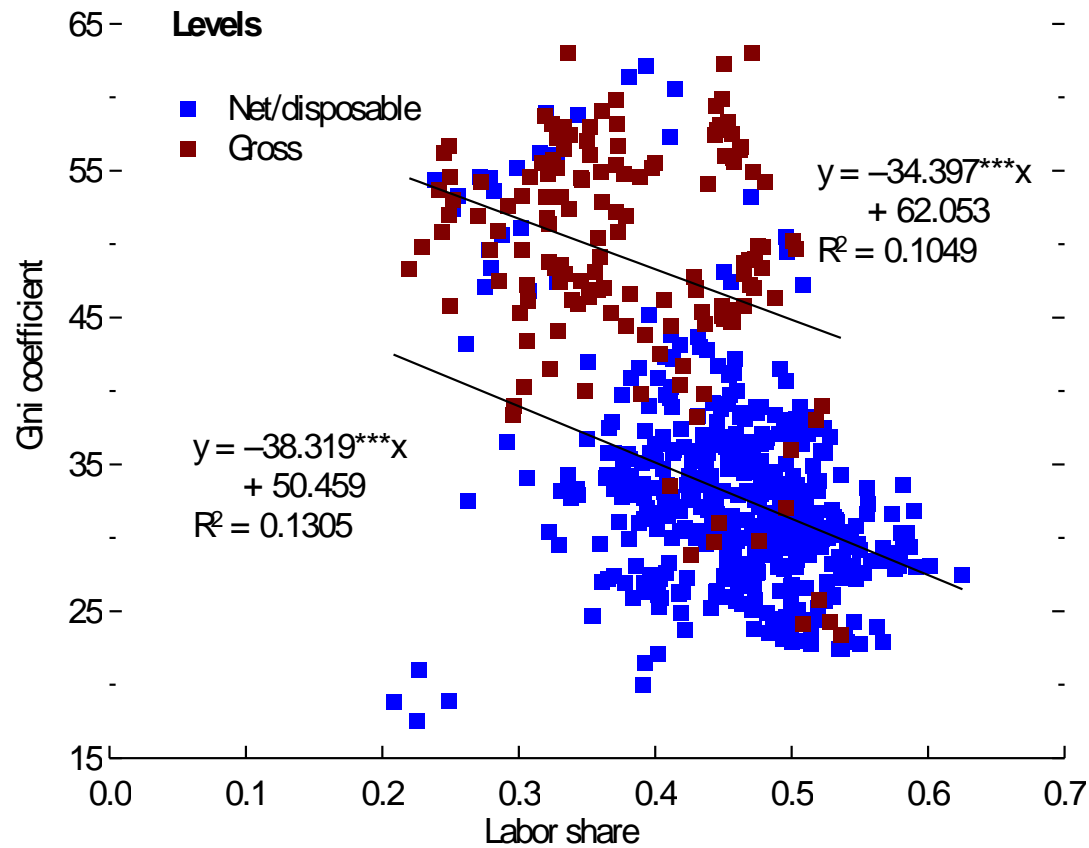

# The global labor share of income has been on a downward trend...

**Evolution of the Labor Share of Income**  
(Percent)

# Declining labor shares are associated with rising inequality.

## Labor Shares and Income Inequality

## Central Questions

- How widespread is the decline in the labor share of income? To what extent have trends in labor income shares differed across countries, industries and skill groups?
- What are the key drivers of the labor share of income and through which mechanisms do they operate?
- Do the drivers vary between advanced economies (AEs) and emerging market and developing economies (EMDEs), industries, and skill groups?
- How have technological advancement and global integration affected labor shares? What has been the role of exposures to routinization and participation in global value chains (GVCs) in declining labor shares?

**How Widespread is the Decline in the Labor Share of Income?**

**What are the Key Drivers of the Labor share of Income?**

# A key parameter that influences labor shares is the elasticity of substitution between capital and labor.

$$\text{Labor share (LS)} = \frac{\text{wage} \times \text{employment}}{\text{wage} \times \text{employment} + \text{rental rate} \times \text{capital stock} + \text{profits}}$$

Cobb-Douglas:  $EoS=1 \Rightarrow$  stable LS

CES:  $EoS \in (0, \infty)$

- Tasks with  $EoS > 1$  automated; technological advances  $\downarrow$  cost of capital  $\downarrow$  LS
- Tasks with  $EoS < 1$  offshored  $\downarrow$  LS

# Changes in labor shares could be driven by:

- **Technology**
  - ↓ relative price of investment goods and cost of automating routine tasks
  - substitution of labor by capital ↓LS if  $EoS > 1$ , i.e. larger effect if more automatable/routinizable
- **Global integration**
  - *Trade in final goods*: specialization in comp. adv. sectors ↓LS in AEs, ↑LS in EMs
  - *Participation in global value chains*: ↓LS in AEs and EMs
  - *Financial integration*
    - Higher capital mobility ↓LS in AEs (lower labor bargaining power);
    - Lower cost of capital ↑LS in EMs.
- **Policy and Institutions**
  - ↓ corporate taxation ↑ after-tax return on capital ↓ LS;
  - ↓ unionization ↓ bargaining power of labor ↓ LS;
  - if labor and product market (de)-regulation ↑ producer rents and markups ↓ LS;
- **Measurement Issues** (self-employment; depreciation of capital)

## ...and will depend on exposures to routinization.

- Routine occupations: easily codified or programmed so they can be executed by a machine; easily automated (substitutable by ICT capital).
- Higher initial exposure of economy/industry to routinizable jobs → greater substitution of labor for capital as the price of capital goods declines → larger decline in labor share.
- Construct sectoral and economy-wide exposures to routinization:
  - occupations are scored on how routine they are (Autor and Dorn 2013)
  - routinization exposures are employment-weighted scores:

$$\text{SECTORAL: } RTI_{sct} = \sum_{o=1}^N \omega_{osct} \times RTI_o$$
$$\text{ECONOMY: } RTI_{ct} = \sum_{o=1}^N \omega_{oct} \times RTI_o$$

$\omega_{osct}$ : employment share of occupation  $o$ , sector  $s$ , country  $c$  at time  $t$

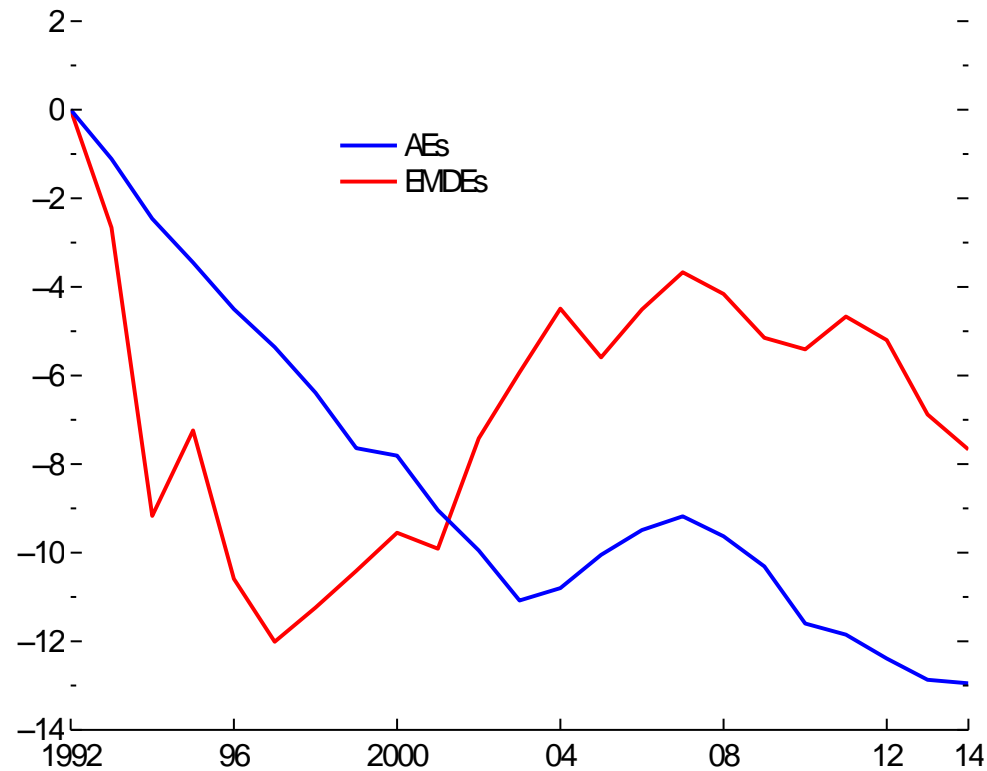

$\omega_{oct}$ : employment share of occupation  $o$ , country  $c$  at time  $t$ ;

$RTI_o$ : routinization score

# The relative price of investment declined more in AEs than in EMDEs...

## Trends in Potential Drivers of Labor Shares: Relative Price of Investment

(Percent change relative to 1990)

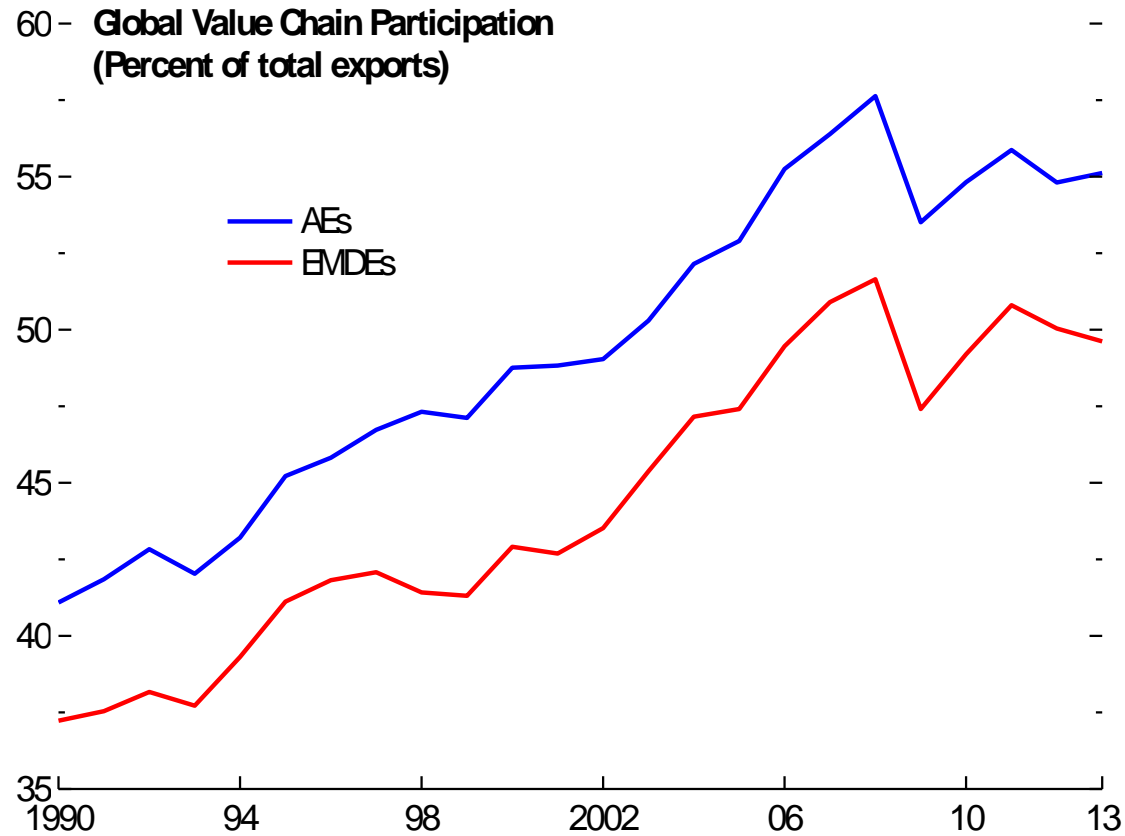

..and countries with higher initial routine exposures experienced larger declines in labor shares.

Trends in Potential Drivers of Labor Shares: Initial Routine Exposure and Changes in the Labor Share

# GVC participation increased; corporate income taxes and union density rates fell.

# Changes in labor shares are mostly due to changes within sectors.

## Shift-Share Analysis

# Empirical Analysis

# Analysis of long changes in aggregate labor shares

- We estimate variants of the baseline regression equation:

$$\widehat{LS}_c = \alpha + \beta_2 \widehat{PI}_c + \underbrace{[\beta_3 RTI_{0,c} + \beta_4 RTI_{0,c} \widehat{PI}_c]}_{\text{Technology}} + \beta_1 \widehat{G}_c + \beta_5 \widehat{Pol}_c + \varepsilon_c$$

- Technology
  - where (hat) variables are long-run annualized changes during 1992-2014 at the country level. (see similar approach by KN, 2013; Elsby, 2013; Acemoglu and Restrepo, 2017)
  - $PI$  is the relative price of investment goods,  $RTI_0$  the initial exposure to routine-biased technological change. Expect  $\beta_2, \beta_4 > 0, \beta_3 < 0$
  - $G$  subsumes variables measuring evolution of global integration: trade in final goods, participation in global value chains, and financial integration (sum of external assets and liabilities net of reserves).
  - $Pol$  summarizes policy/institutional factors: Unionization, Corporate taxation, EPL, PMR.

# Technology is the key driver of labor shares in AEs, GVC participation in EMs.

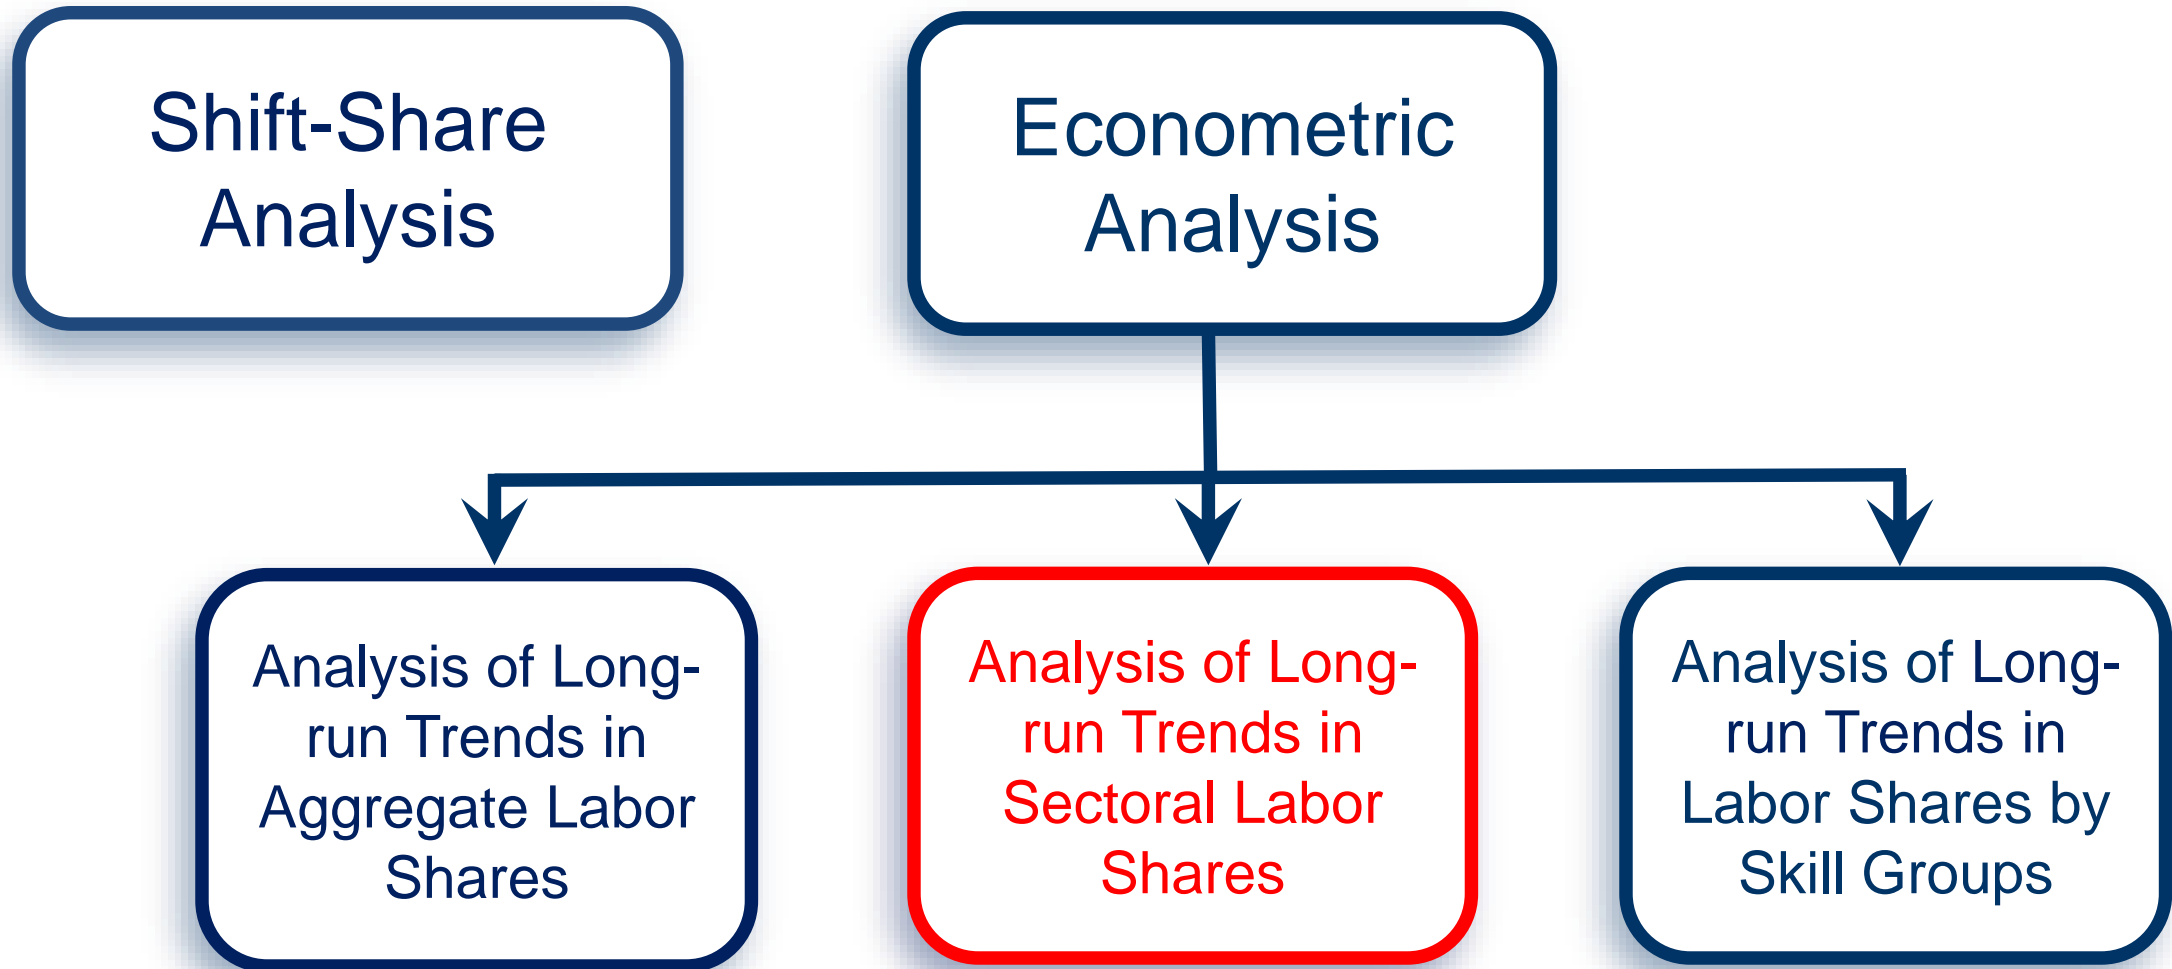

## Aggregate Results: Contributions to Aggregate Labor Share Changes, 1993–2014

(Deviation from regression constant)

- A decline in the relative price of investment of 15 pct over 1990-2014 implies 0.4 ppt fall in LS in countries with low exposure, 1.7 ppt fall in countries with high exposure to routine-biased technological change. (Median was -3 ppt among countries with declining LS)
- An increase in intermediate trade by 4 pct of GDP (median increase in sample) implies a fall in LS of 1.6 ppt.
- Effect of corporate tax and financial integration small in comparison (or offsetting).

# Empirical Analysis

# Aggregate evolutions conceal heterogeneity across sectors.

## Heterogeneity across Sectors and Countries

# Analysis of long changes in sectoral labor shares

- Empirical strategy similar to analysis of aggregate labor shares.
- Link long changes in labor shares to the long changes in relative price of investment goods (PI); changes in measures of global integration (G) including final goods trade, intermediate trade, and cross-border capital mobility, and initial exposures to routinization (RTI), including in its interaction with the relative price of investment goods.
- Variants of the following cross-sectional regressions ( $c=1,\dots,C$ ,  $s=1,\dots,S$ ) are estimated.

$$\widehat{LS}_{cs} = \beta_1 \widehat{PI}_{cs} + [\beta_2 RTI_{0,cs} + \beta_3 RTI_{0,cs} \widehat{PI}_{cs}] + \beta_4' \widehat{G}_{cs} + \gamma_0' FE_c + \gamma_1' FE_s + \varepsilon_{cs}$$

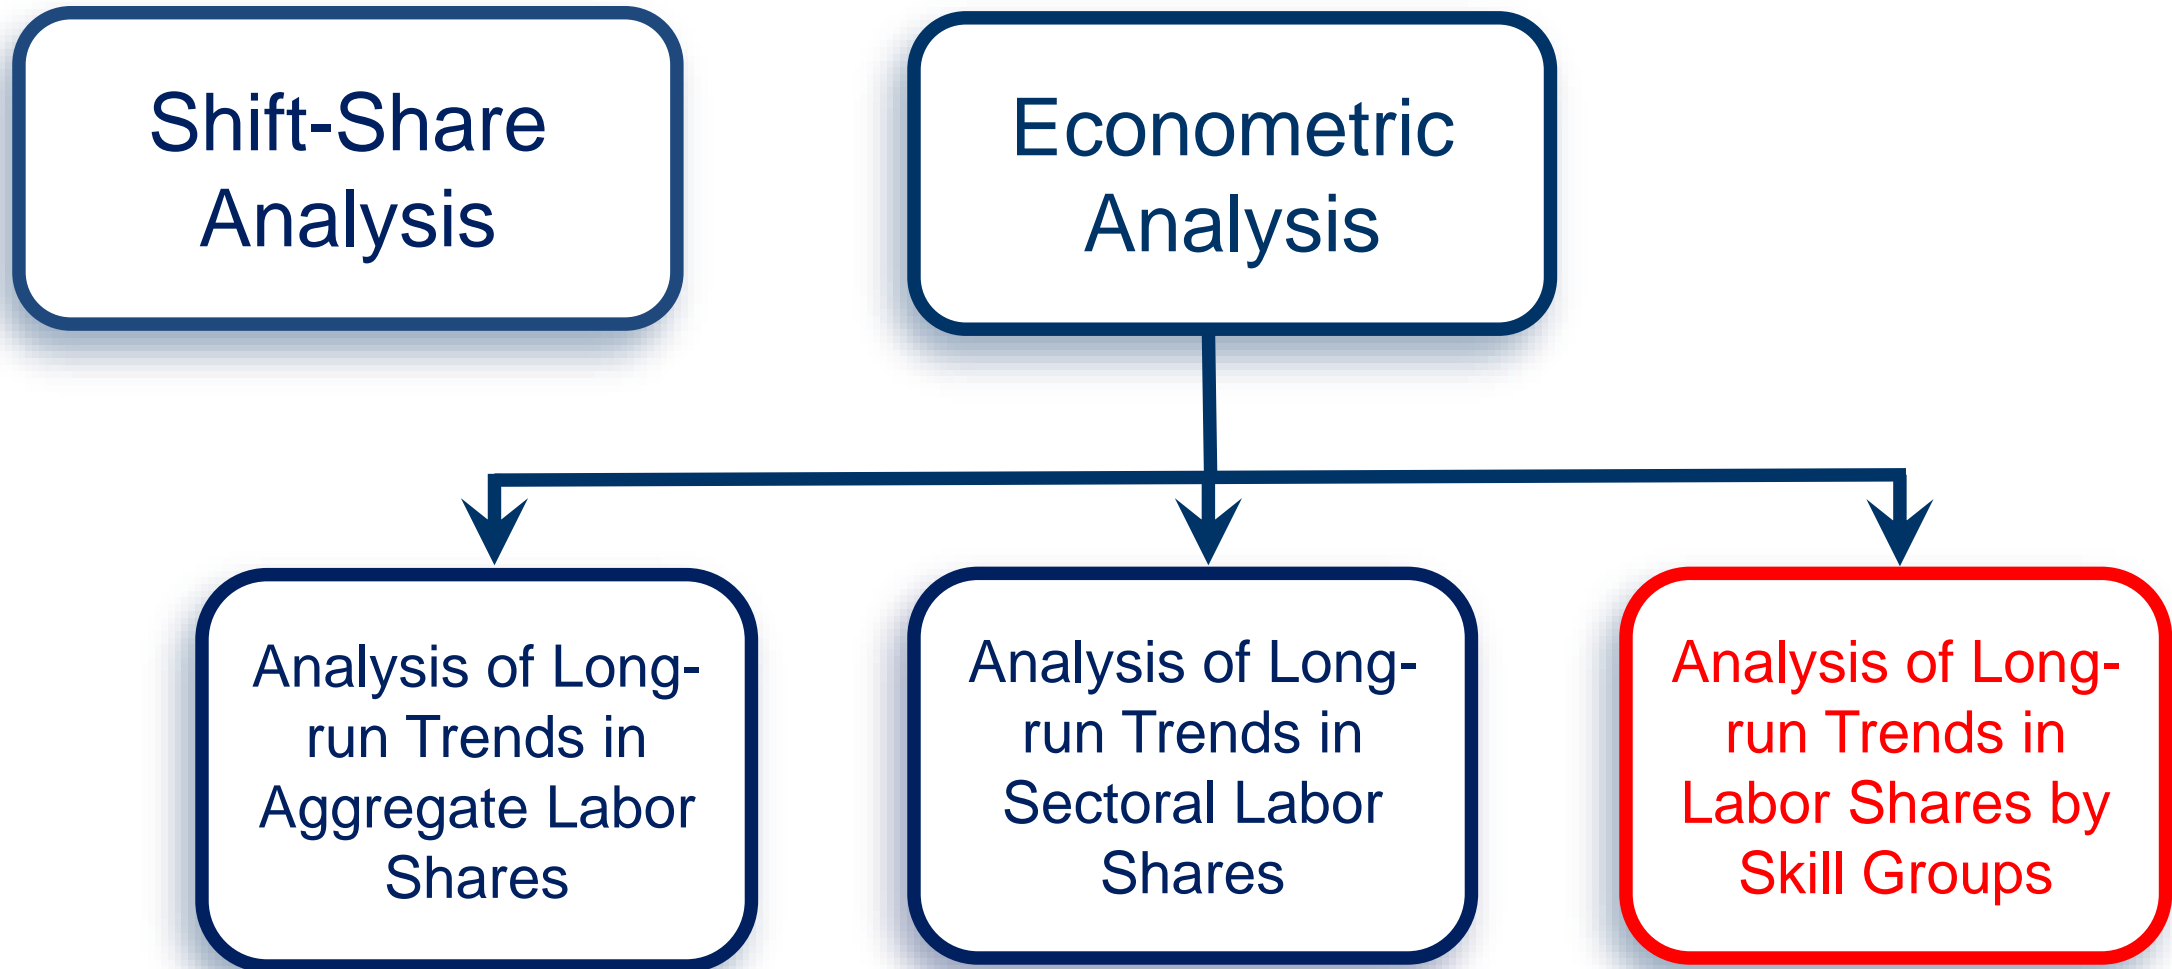

# GVC participation is associated with declines in labor shares only in tradable sectors.

## Sectoral Results, Advanced Economies: Contributions to Sectoral Labor Share Changes

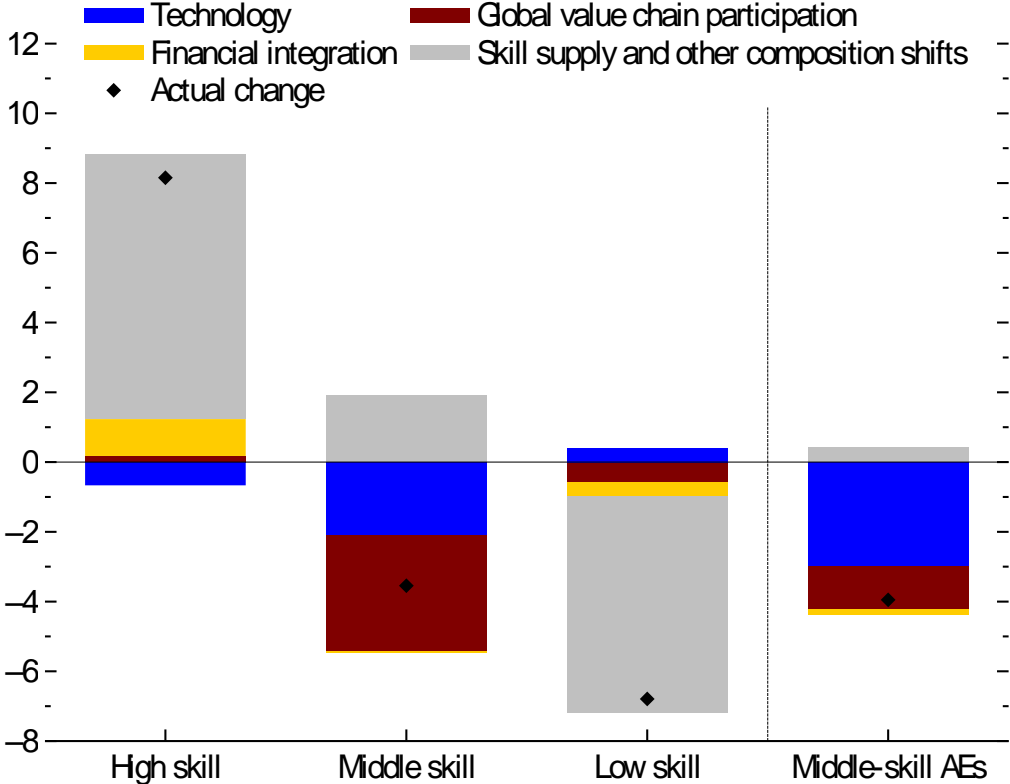

- Median decline in relative price of investment -> decline in LS observed in country-sector at the 25<sup>th</sup> percentile of routinization.
- Effect of a decline in relative price of investment is double that at the 75<sup>th</sup> percentile of routinization.
- Move from 25<sup>th</sup> to 75<sup>th</sup> percentile of routinization distribution roughly matches observed difference.

# Empirical Analysis

# Technological progress and GVC participation hollow out the medium-skilled.

Contributions to Aggregate Labor Share Change by Skill, 1995–2009

# Conclusions

- The decline in the labor share of income in advanced and emerging market economies conceals heterogeneity across countries, sectors and skill levels, with the medium-skilled seeing the sharpest declines.
- Overall, the declines in the labor share of income are mostly due to within-sector declines not reallocation across sectors.
- In AEs, technological advancement has been the key driver of the evolution of labor shares.
- In EMs, participation in GVCs played a larger role, though could reflect benign changes.
- Technological advancement and GVC participation affected labor shares largely through their impact on middle-skilled labor.

# Policy Implications

- Policies should depend on country circumstances: level of development, extent of decline in labor shares, relative importance of underlying drivers, and existing social safety nets.
- In AEs:
  - help workers cope with disruptions, including through skill upgrading and facilitating transitions,
  - long-term investment in education,
  - longer-term redistributive measures in line with social contract.
- In EMs:
  - Decline in labor share by itself may not call for policy intervention, but gains from growth should be shared more broadly.
  - Challenges similar to those in AEs could arise as automation progresses – promote skill deepening to prepare for further structural transformation.
