

Rethinking Energy Policies in Europe Following the Ukraine War: How to Support the Vulnerable and Speed up the Green Transition

JVI WEBINAR, NOVEMBER 29, 2022

Ian Parry and Karlygash Zhunussova
Fiscal Affairs Department, IMF

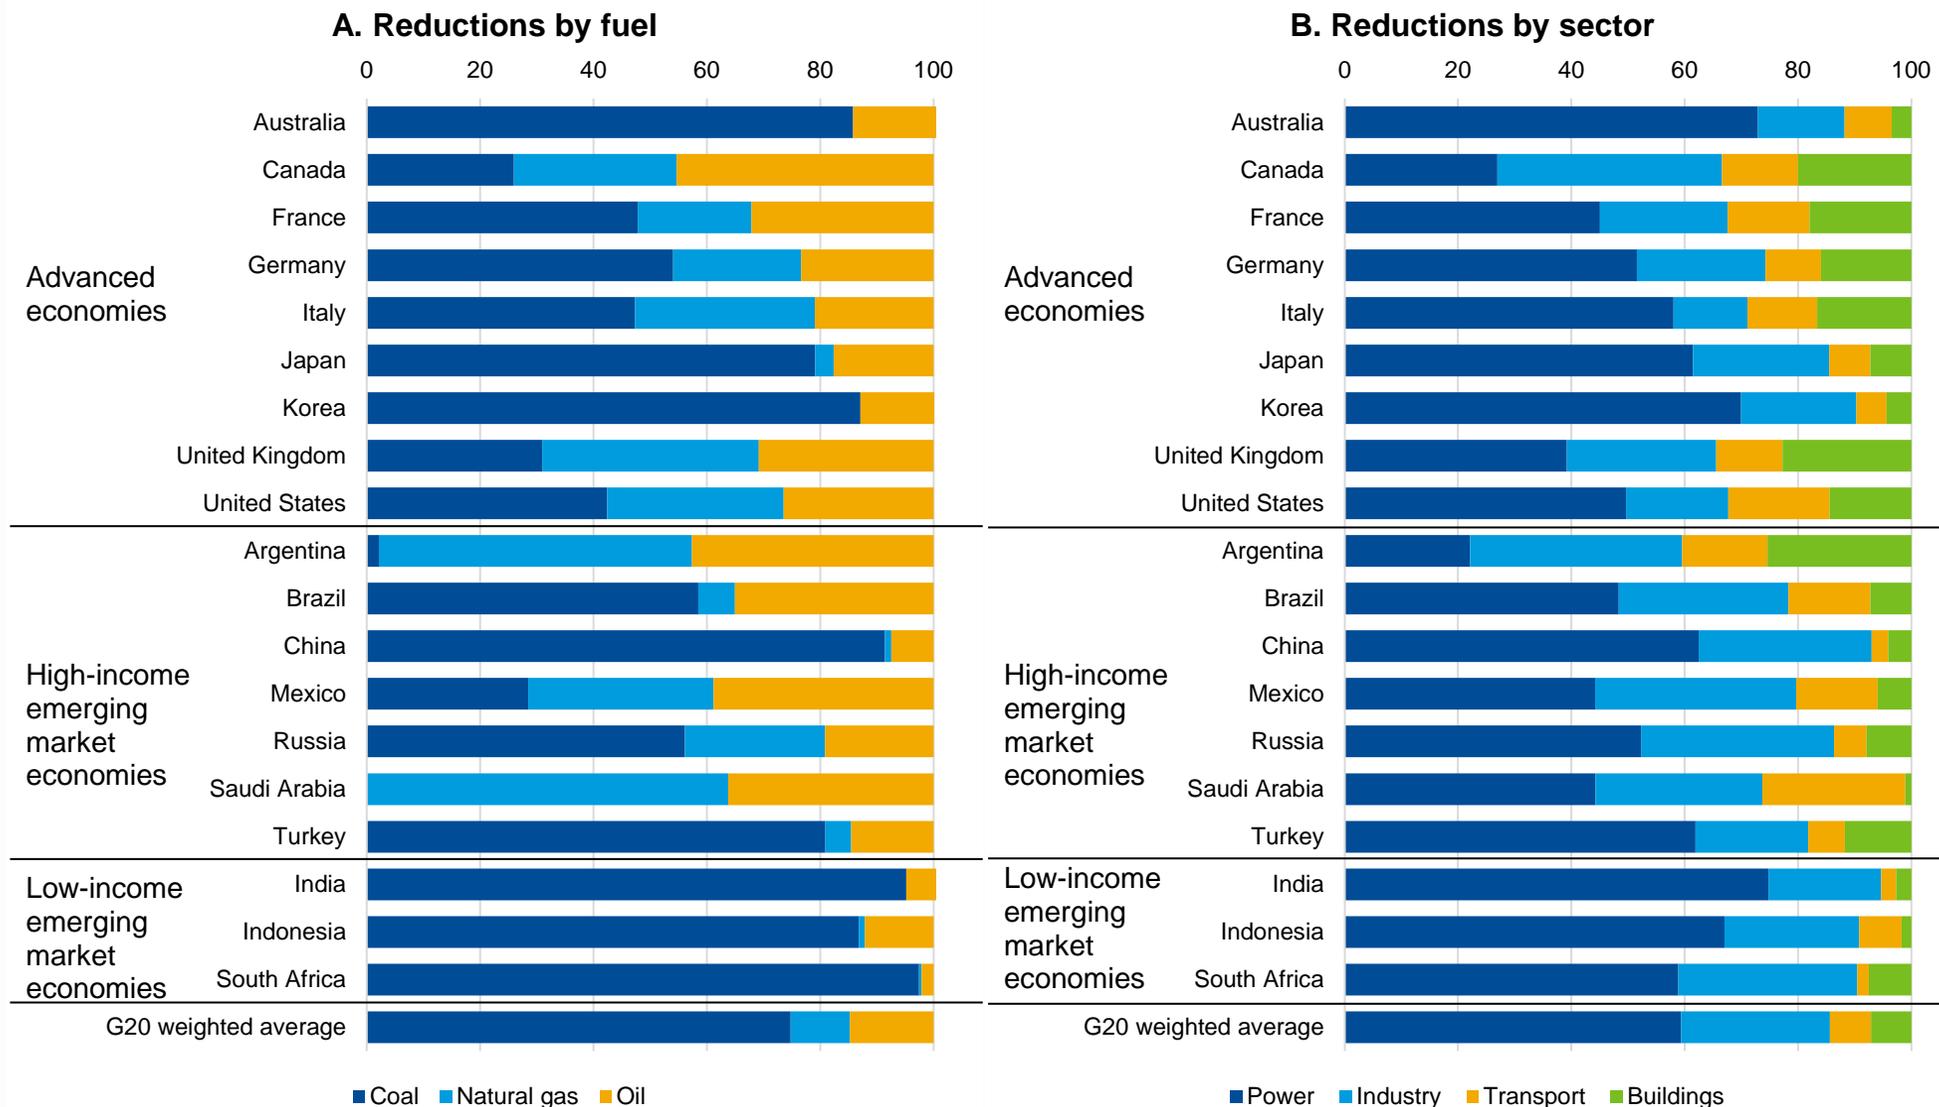

Contents

- Carbon pricing
- Reinforcing sectoral instruments
- International coordination
- Implications of energy price surge for mitigation
- Impacts of mitigation policies

Carbon Pricing

Coverage: Coal or Power/Industry Most Important

Breakdown of CO₂ Reductions by Fuel/Sector under Carbon Pricing, 2030

Source: IMF staff from CPAT.

Note: Estimates are for a \$75/50/25 carbon price for advanced/high-income emerging/low-income economies. Panel B is for direct emissions. Buildings includes fossil fuel CO₂ emissions from residences, services, agriculture, and forestry but emissions from industrial buildings are included under industry.

Comparison of Carbon Taxes and Emissions Trading

Design issue	Instrument	
	Carbon tax	ETS
Administration	Administration is more straightforward (e.g. as extension of fuel taxes)	May not be practical for capacity constrained countries
Uncertainty: price	Price certainty can promote clean technology innovation and adoption	Price volatility can be problematic; price floors, and cap adjustments can limit price volatility
Uncertainty: emissions	Emissions uncertain but tax rate can be periodically adjusted	Certainty over emissions levels
Revenue: efficiency	Revenue usually accrues to finance ministry for general purposes (e.g., cutting other taxes, general investment)	Free permit allocation may help with acceptability but lowers revenue; tendency for auctioned revenues to be earmarked
Revenue: distribution	Revenues can be recycled to make overall policy distribution neutral or progressive	Free allowance allocation or earmarking may limit opportunity for desirable distributional outcomes
Political economy	Can be politically challenging to implement new taxes; use of revenues and communications critical	Can be more politically acceptable than taxes, especially under free allocation
Competitiveness	Border carbon adjustment more robust than other measures (e.g., threshold exemptions, output-based rebates)	Free allowances effective at modest abatement level; border adjustments (especially export rebate) subject to greater legal uncertainty
Price level and emissions alignment	Need to be estimated and adjusted periodically to align with emissions goals	Alignment of prices with targets is automatic if emissions caps consistent with mitigation goals
Compatibility with other instruments	Compatible with overlapping instruments (emissions decrease more with more policies)	Overlapping instruments reduce emissions price without affecting emissions though caps can be set or adjusted accordingly
Pricing broader GHGs	Amenable to tax or proxy taxes where they build off business tax regimes; feebate variants are sometimes appropriate (e.g., forestry, maritime)	Less amenable to ETS; incorporating other sectors through offsets may increase emissions and is not cost effective
Global coordination regimes	Most natural instrument for international carbon price floor	Can comply with international price floor; mutually advantageous trades from linking ETSs but does not meet global emissions

Reinforcing Sectoral Instruments

Pricing should be Complemented with Sectoral Instruments

- Due to acceptability constraints on pricing (especially when energy prices high)
- Regulations (e.g., renewable shares) and subsidies (e.g., electric vehicles) are common
- But feebates more flexible and cost effective
 - ▶ Revenue neutral sliding scale of fees/rebates for products/activities with $>/<$ average CO₂ rates
 - ▶ Fiscal analogue of tradable emission rate standard (e.g., Canada)
- Attractions of feebates
 - ▶ Promote all responses for reducing emissions intensity (though no demand response)
 - ▶ Cost effective (regulations require fluid credit trading)
 - ▶ Avoid a fiscal cost (unlike subsidies)
 - ▶ No burden on average household/firm (unlike carbon pricing)

Applications of Feebates

Energy Sector

- Vehicles (commonly integrated into registration fees)
- Power generation/industry (limits increase in prices/production costs)
- Buildings (encourage renovations, clean heating, efficient appliances)
- Industry (limits competitiveness/leakage concerns)

Broader sectors

- Forestry
 - ▶ Landowners: $\text{fee} = \text{CO}_2 \text{ price} \times (\text{baseline carbon storage} - \text{current storage})$
- Extractives (methane)
 - ▶ Revenue neutral shift of current fiscal regimes
 - ▶ Proxy pricing based on default emission rates with rebates for cleaner firms

International Coordination Mechanisms

Coordination Regimes to Reinforce Paris

2030 gaps to address

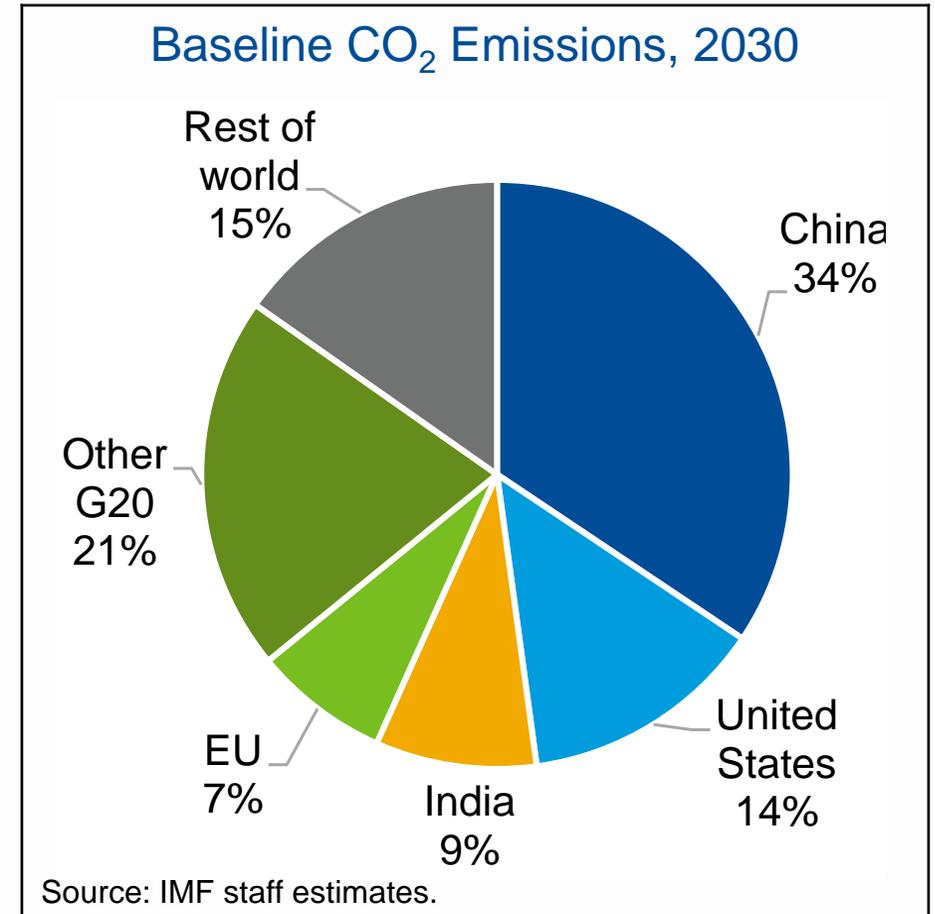

- *Ambition*: Pledged reductions only 1/3-2/3 of needed
- *Policy*: Global CO₂ price > \$75 per tonne needed

Difficulties in Paris Agreement

- *Negotiation*: too many parties/parameters
- *Unilateral policy*: deterred by competitiveness

Elements of coordination regimes

- Small number of large emitters
- Minimum carbon price

Coordination Regimes to Reinforce Paris

Differentiated responsibilities

- Differentiated floors/support for low-income countries
- \$75/50/25 floor price aligns global emissions with <2C with 6 participants

Accommodate non-pricing approaches

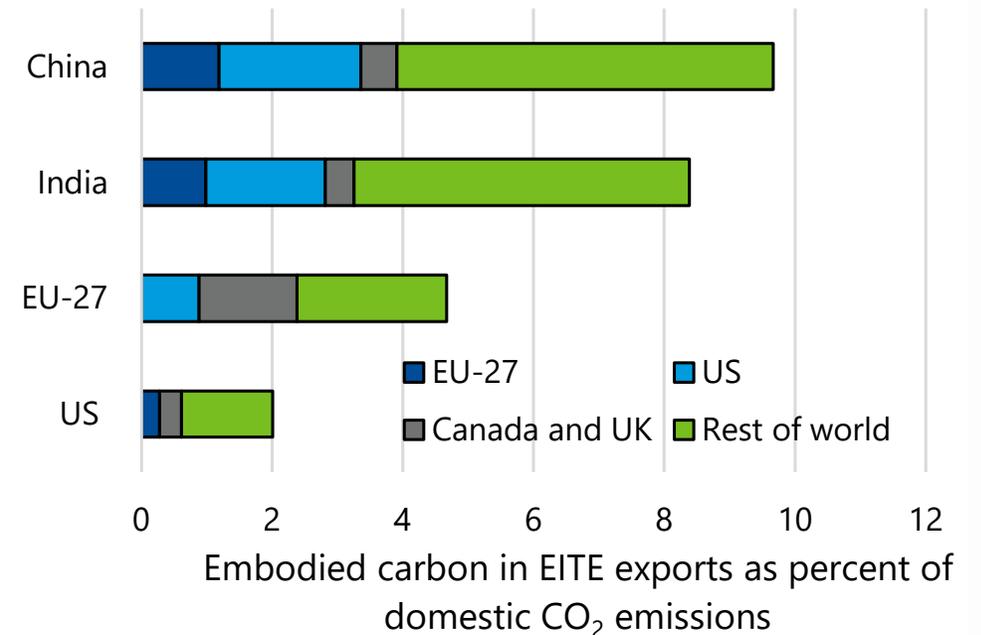

- CPAT maps other policies into CO₂ reductions/carbon price equivalent

Alternative coordination through carbon markets

- Must accommodate countries without ETS
- Address equity
- Needs prices/caps aligned with temp. goals

Unilateral Border Adjustment Regime is Ineffective

Fraction of Domestic Carbon Emissions Embodied in EITE Exports to Trading Partners, 2015

Source: OECD (2021). EITE = energy-intensive, trade-exposed.

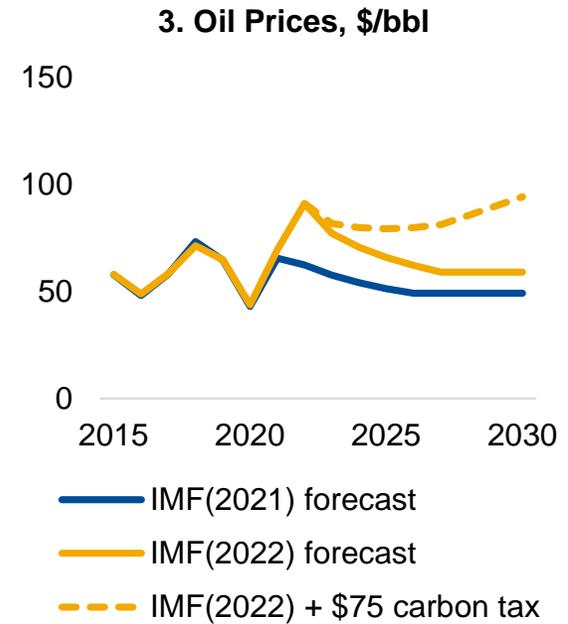

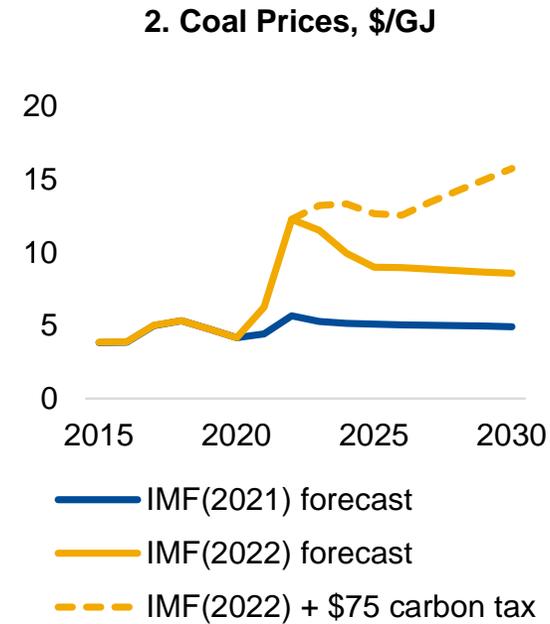

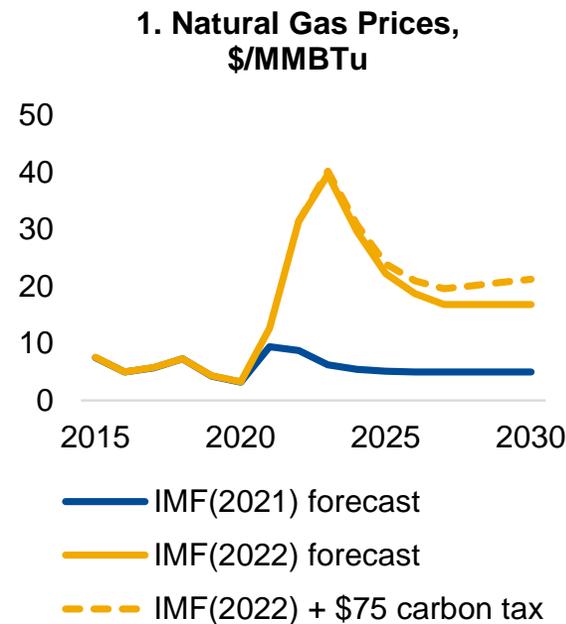

Implications of Price Surge

Implications of Energy Price Surge

- Underscores urgency of transition: to clean/secure energy
- Household assistance: targeted/unrelated to energy use
- Modest emissions impact: gas/coal price increased, surge is partially temporary

Carbon price signal needed

- Receding fuel prices → time to lock in pricing
- Affects pricing/non-pricing policy balance

Impacts of Mitigation Policies

The Climate Policy Assessment Tool (CPAT)

Helps policymakers design, compare, and implement policies to achieve NDCs and SDGs

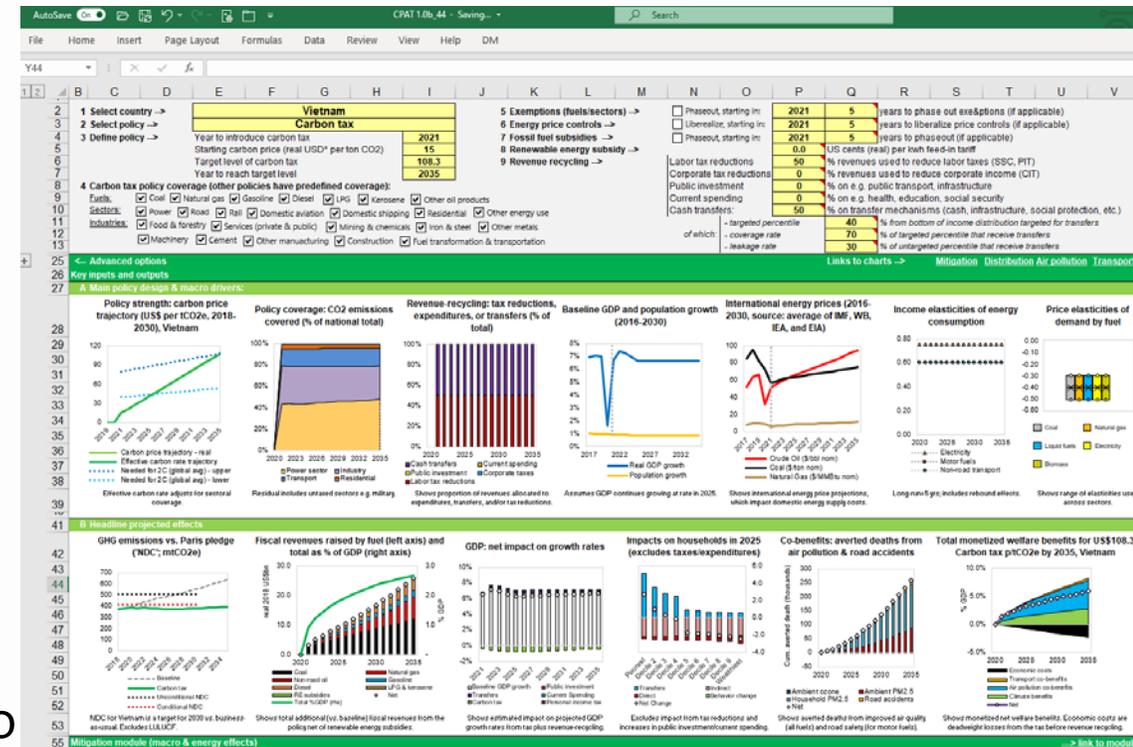

- Spreadsheet 'model of models' covering > **200 countries**
- **Developed jointly** by IMF (FAD) & World Bank (SD & EFI)
- Aimed at **economists** in IMF, WB; finance, planning & line ministries

Policies

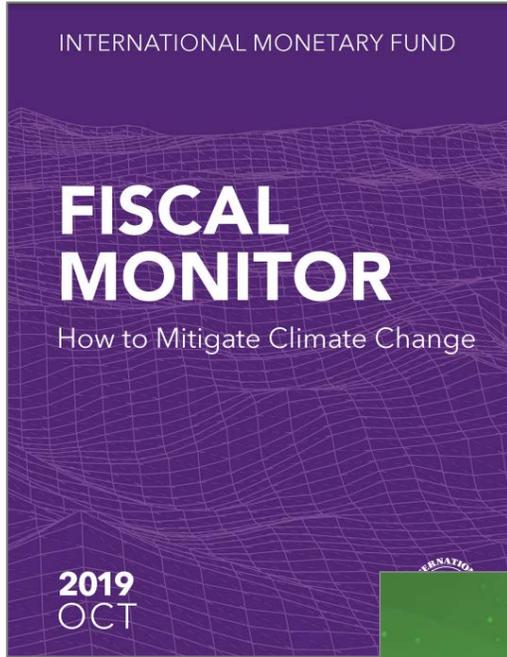

- Carbon pricing, fuel tax reform, performance standards, clean technology subsidies

Metrics

- **energy & emissions** – prices, consumption, fuel mix, global and local pollutants
- **macroeconomic** – GDP, revenues, welfare cost, trade balance
- **distributional** – by income group, region, industry
- **co-benefits** – pollution/mortality, road safety, congestion

Technical Report | November 2022

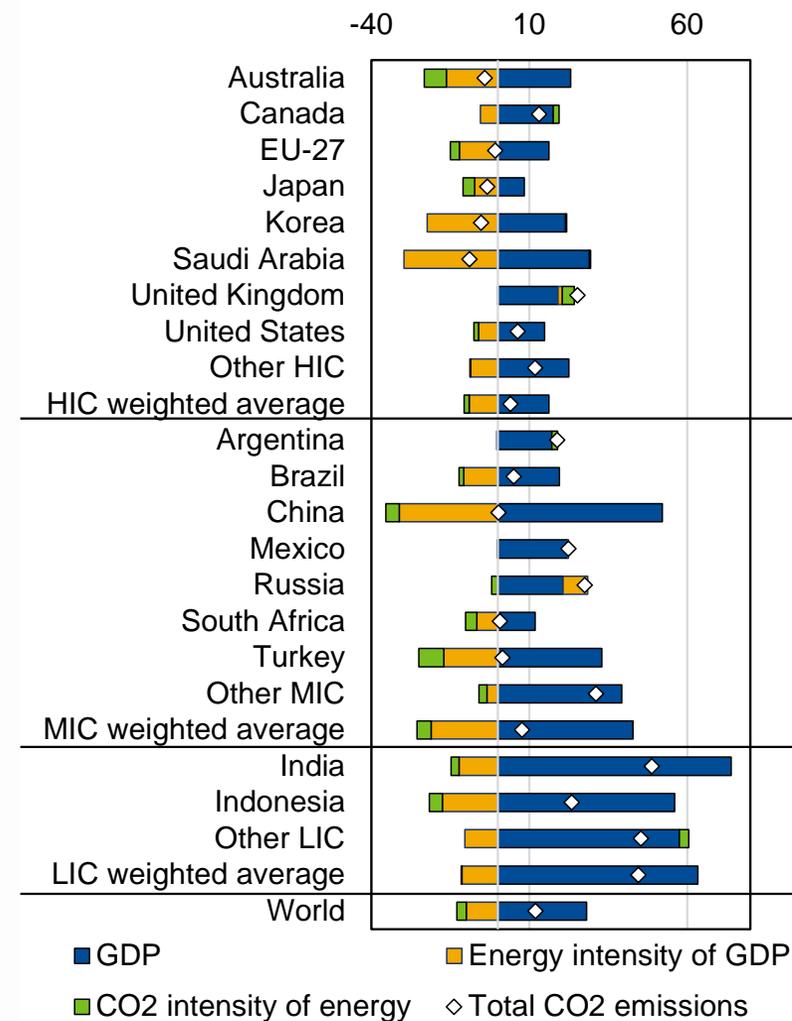

INTERNATIONAL MONETARY FUND

If no action taken emissions will continue to grow

Global GHG Emissions, Nationally Determined Contributions (NDCs), and Temperature Targets

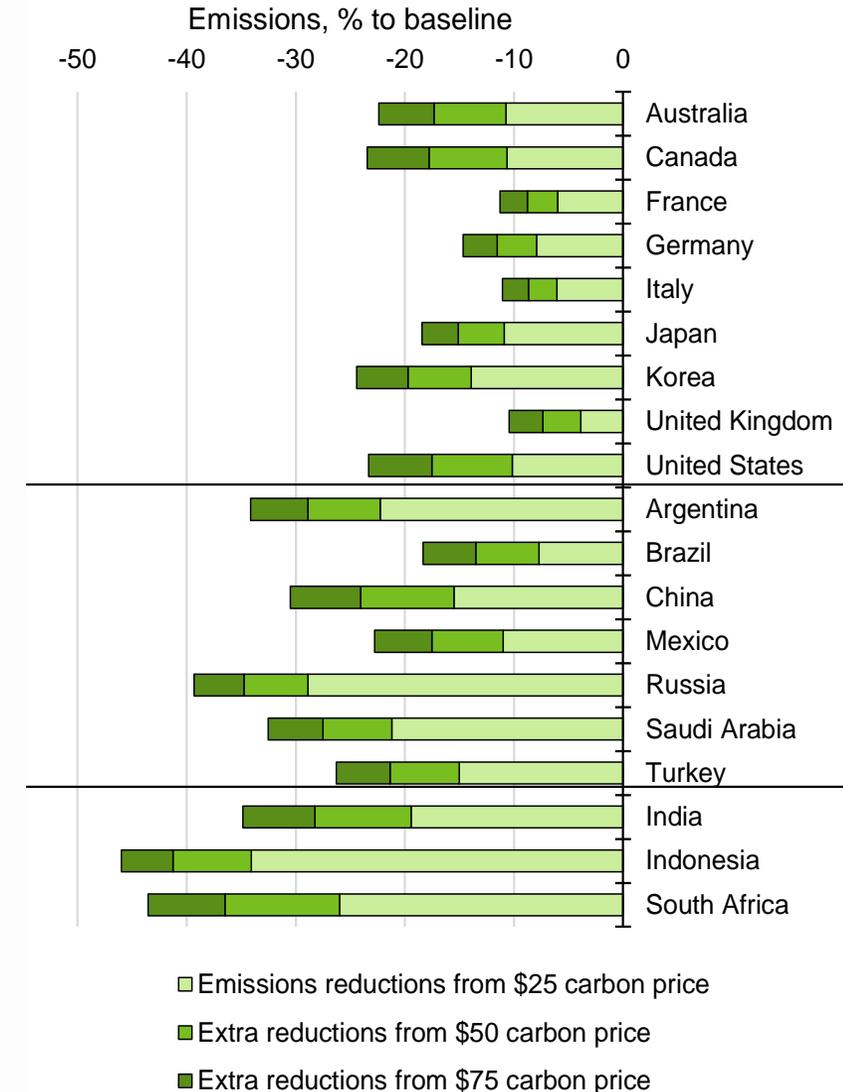

Drivers of CO₂ emissions growth

Carbon pricing can reduce emissions...

- Heterogeneous responsiveness to carbon pricing across countries:
 - ▶ \$50/tonne in 2030 cuts some middle-income country emissions **up to 30%**
- A **\$75+** carbon price is needed to reduce G20 emissions **consistent with 2°C**

CO₂ Emissions Impacts from Carbon Pricing, G20 Countries, 2030

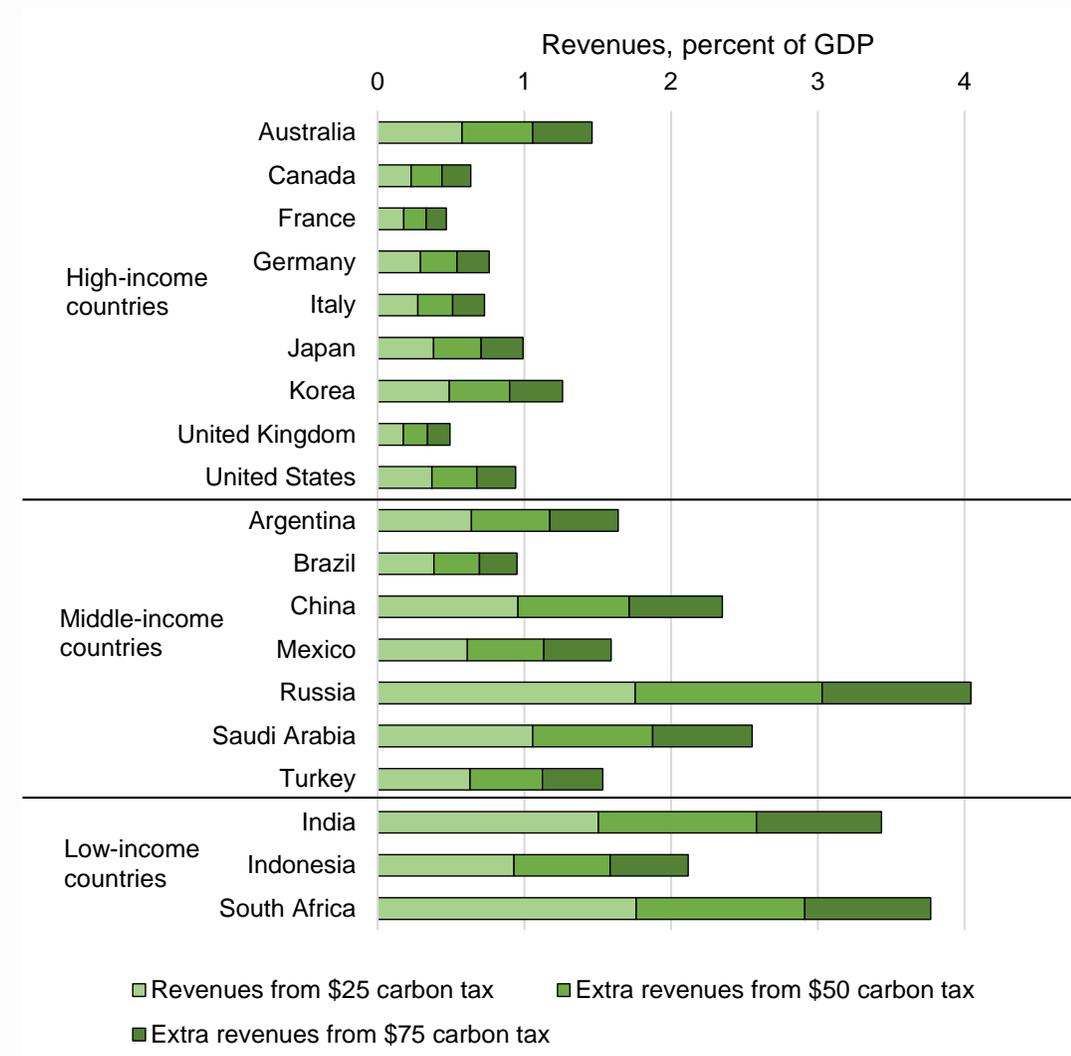

... while raising significant revenues

- Relatively higher revenue potential in middle/low-income countries:
 - ▶ Low-income: ~ **1.4%** for \$25/tonne
 - ▶ Middle-income: ~**1%** for \$50
 - ▶ Emission-intensive: **2-3%** for \$50

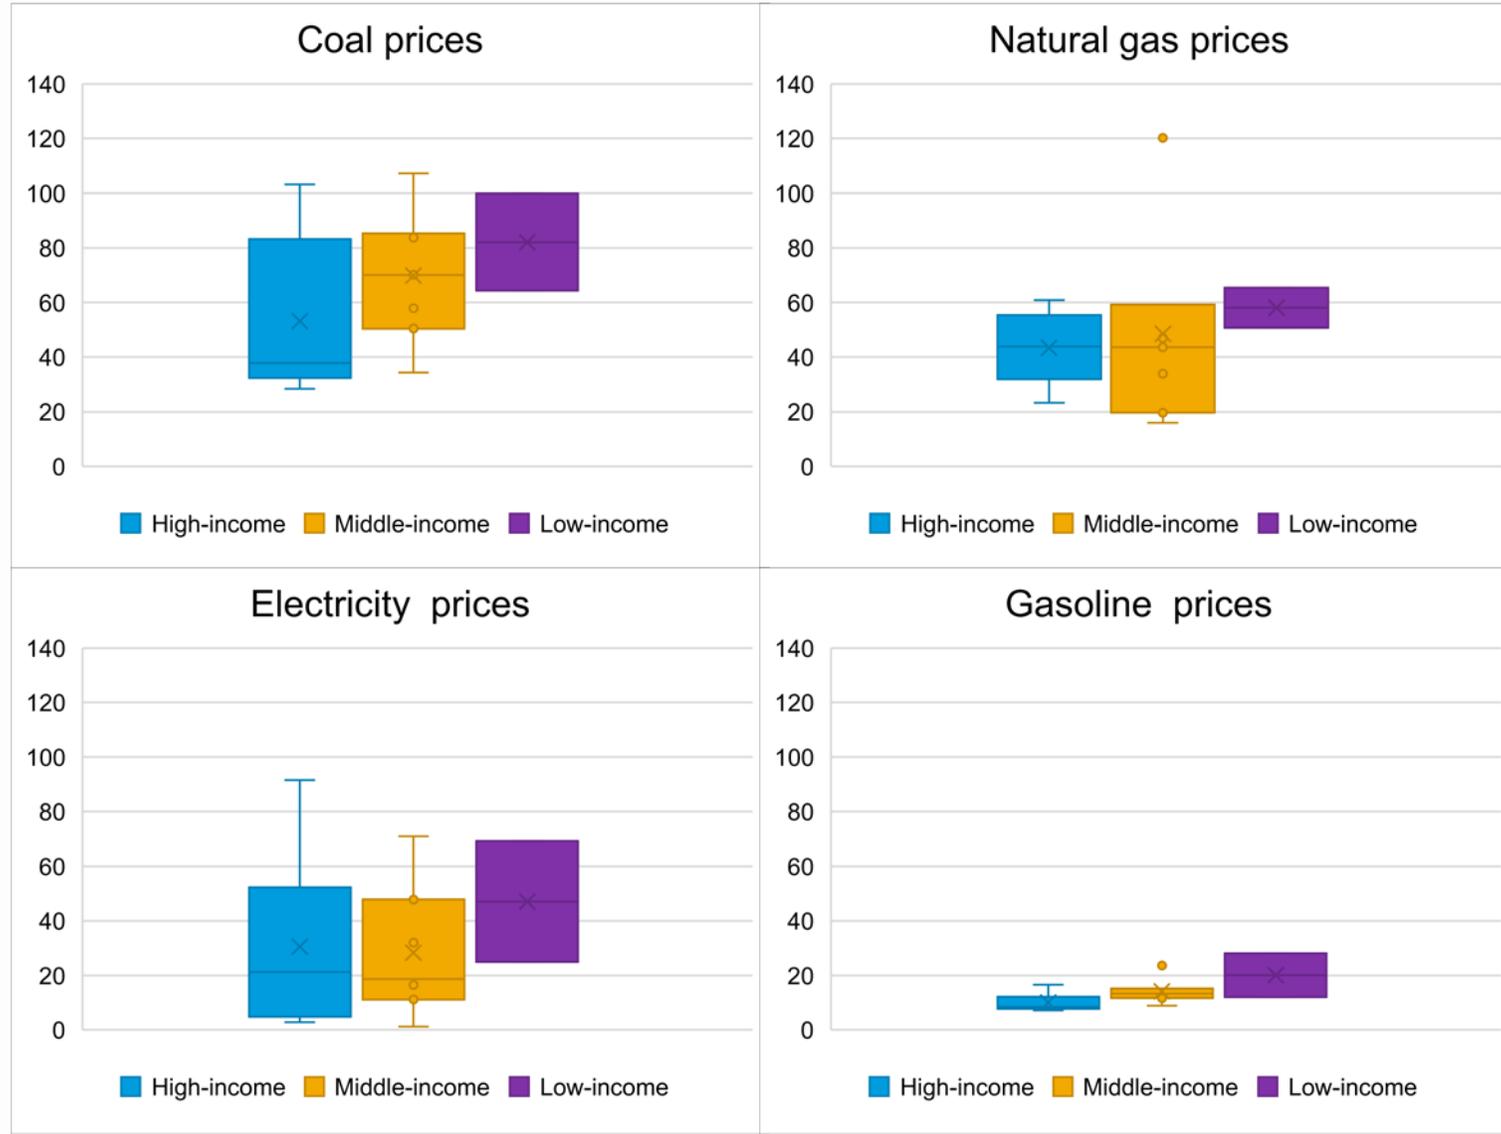

- More moderate revenues in high-income
 - ▶ **0.5-1.5%** for \$75

Revenues from carbon pricing, G20 countries, 2030

Carbon pricing schemes increase energy prices...

Impact of \$50 carbon price on energy prices, 2030

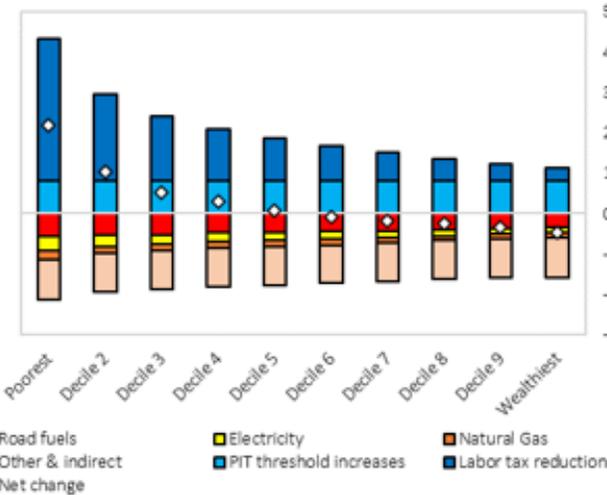

Revenue recycling contains household burdens

Household Burdens from Carbon Pricing, 2030

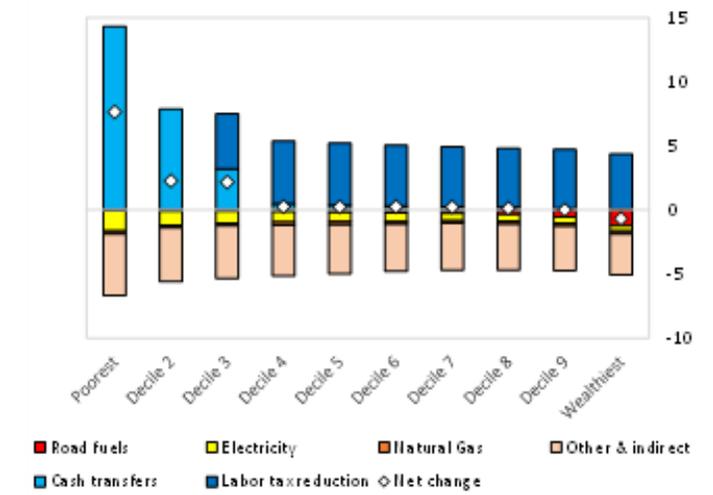

- First-round impact on households is moderately regressive or neutral
- Revenue recycling could offset ~ 80-90% of average household burden
 - ▶ ... and make the reform progressive and pro-poor

(% Relative to Pre-Policy Household Consumption)

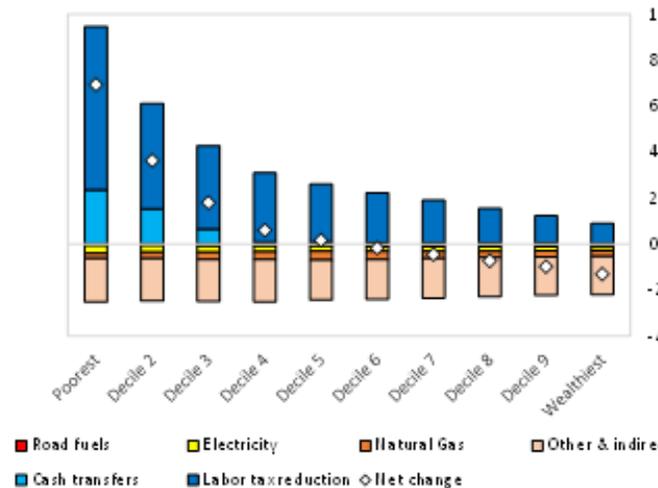

United States (\$75 carbon tax)

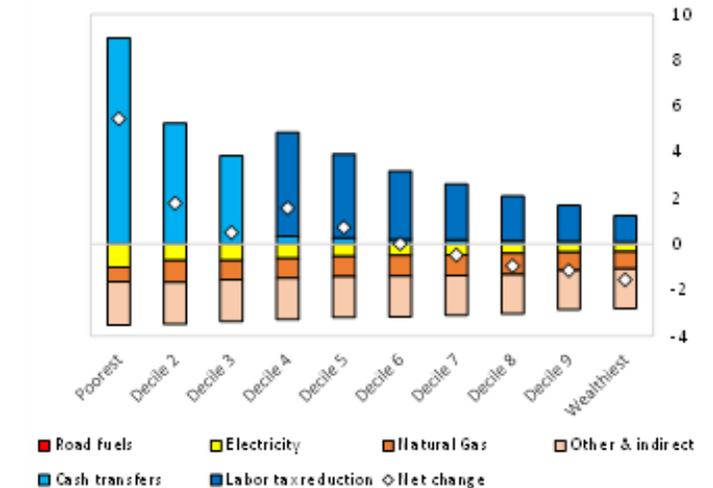

China (\$50 carbon tax)

Turkey (\$50 carbon tax)

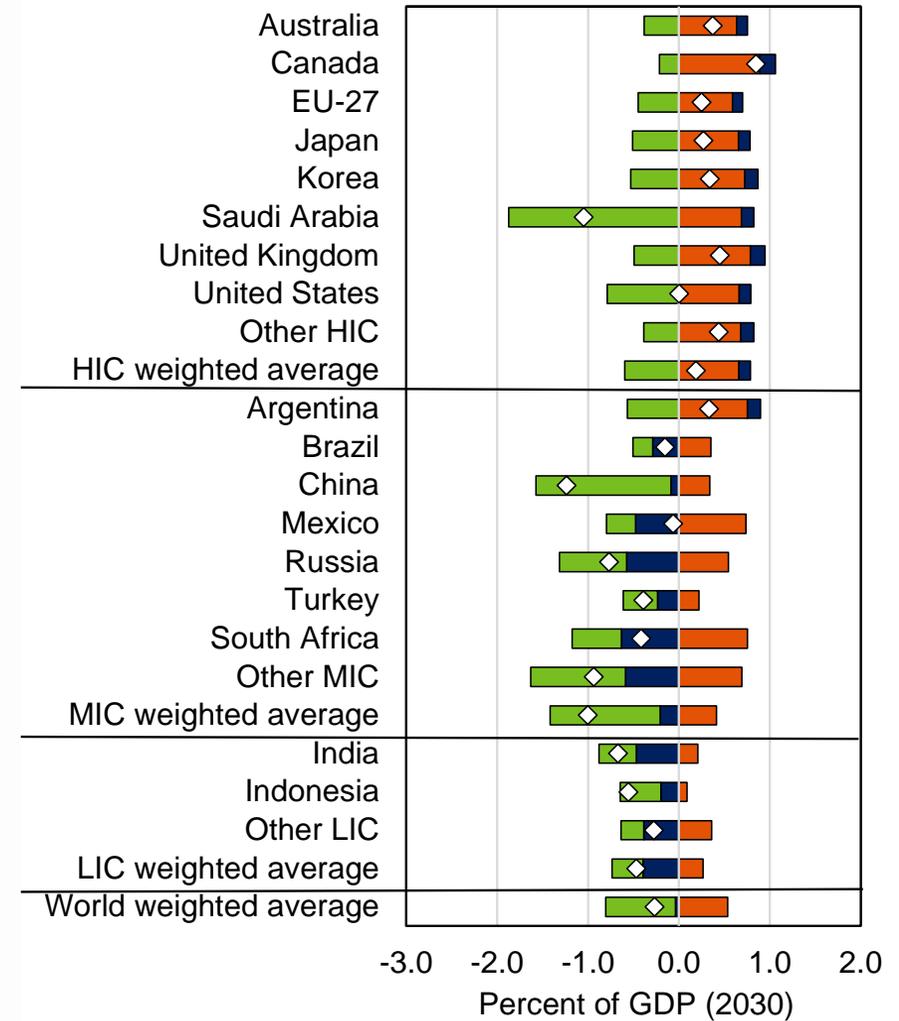

Argentina (\$50 carbon tax)

Domestic environmental co-benefits can outweigh costs

Abatement Costs/Co-Benefits from Carbon Pricing, 2030

- Co-benefits include reductions in:
 - ▶ local air pollution mortality,
 - ▶ road congestion,
 - ▶ accident externalities

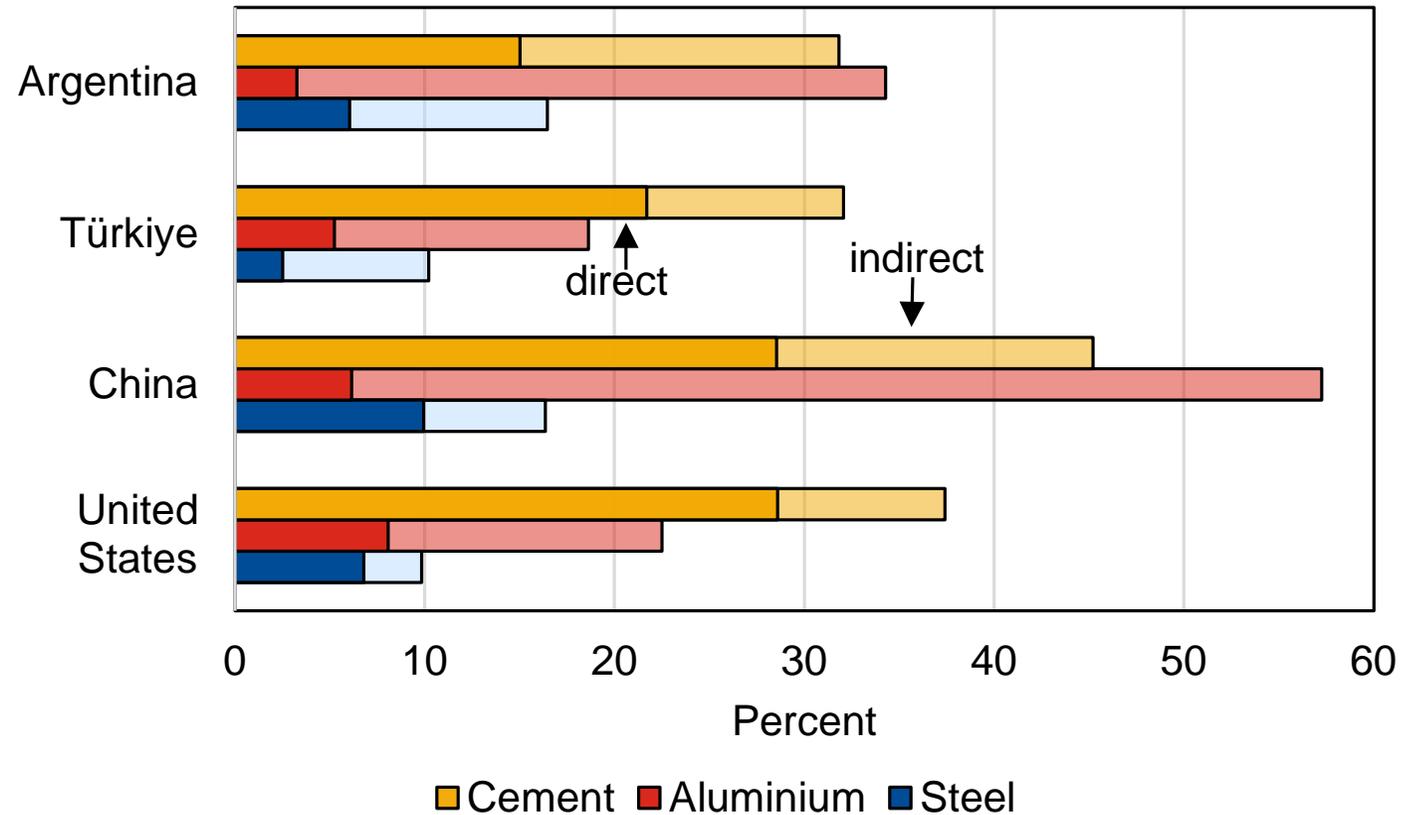

■ Pure mitigation costs
■ Potential fiscal benefit
■ Domestic environmental co-benefits
◇ Net effect

Energy-intensive, trade-exposed (EITE) industries

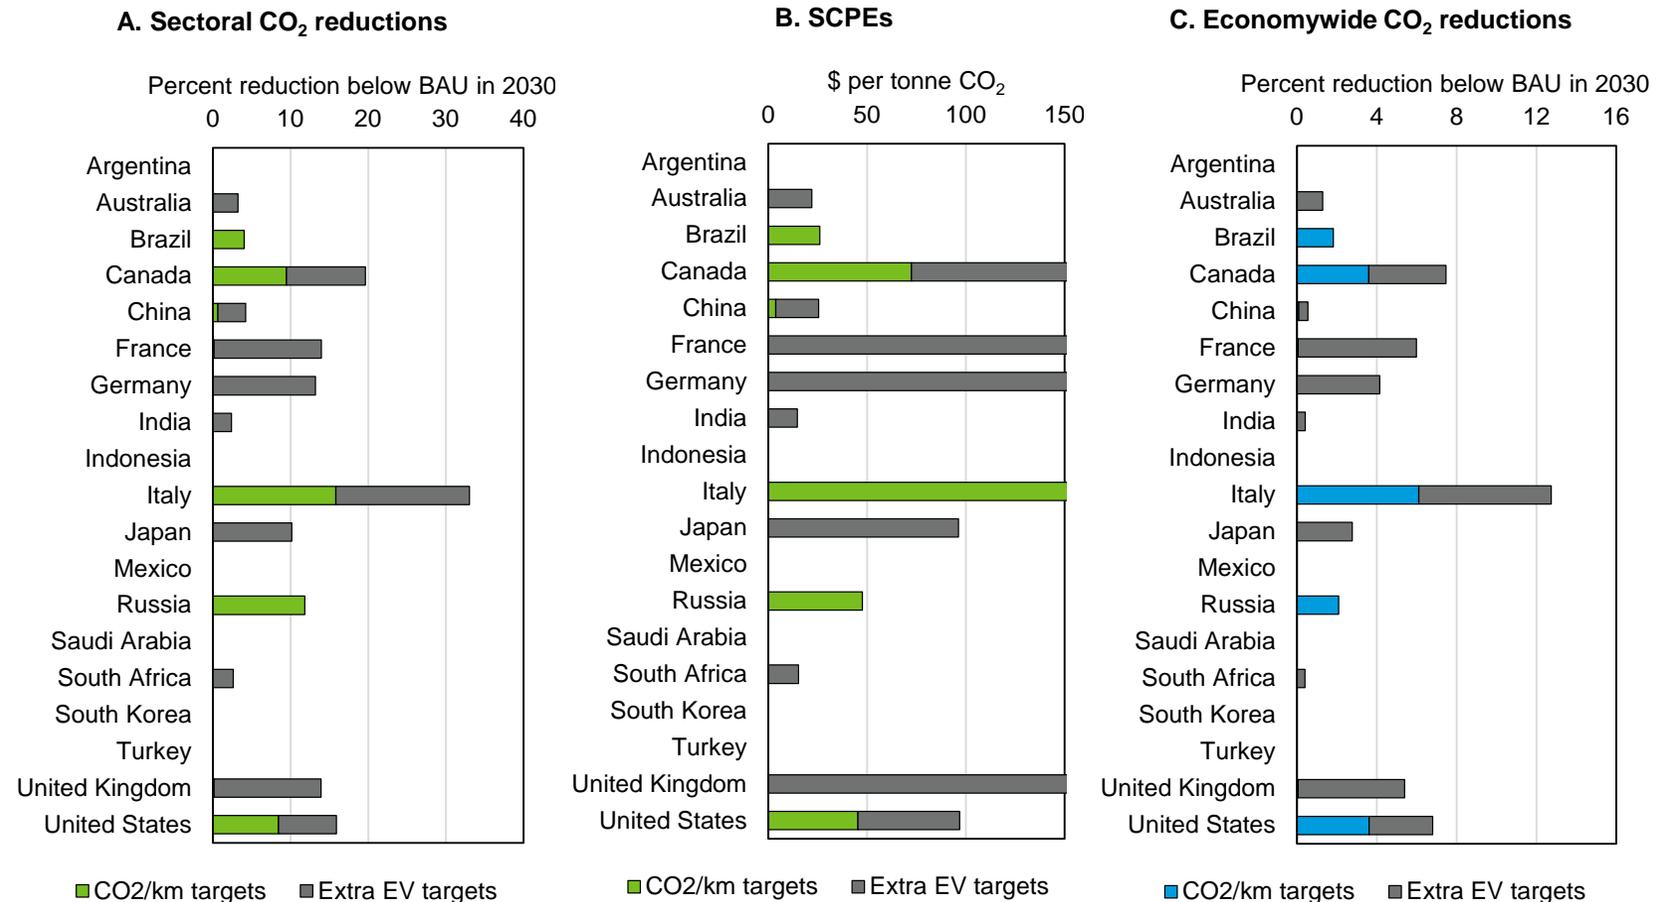

- Mainly these industries have
 - ▶ high embodied carbon
 - ▶ limited ability to pass production cost increases forward into higher consumer prices
- Direct cost increases 5-10% percent for aluminum/steel but ≤ 30% for cement
- Relatively large indirect cost increases (carbon embodied in electricity inputs)

Production Cost Increases for Selected EITE Industries from \$75/50 Carbon Price, 2019

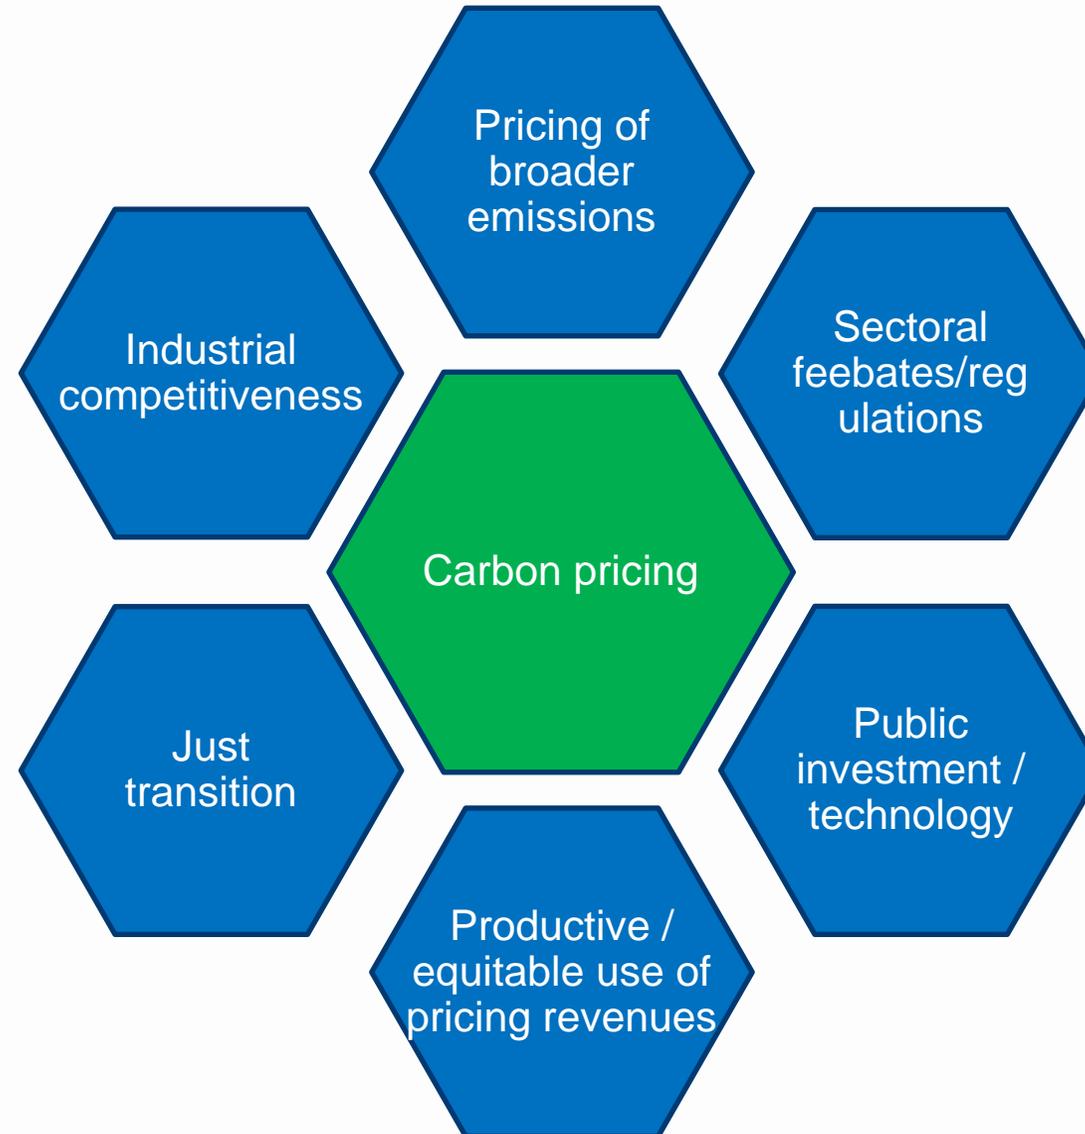

Other mitigation policies at the sectoral level can be effective at reducing emissions

Transport Sector Targets

SCPEs = sectoral carbon price equivalents

Supporting Policies Needed to Enhance Effectiveness and Acceptability of Mitigation Strategy
